# COMP 421: Files & Databases

Lecture 10: It's Data Structure Week! (Or, what Ben did at his conference)

#### **Announcements**

Project 2 has been released! Get started!

Necessary material on B+Tree latching this Wendesday in class.

**Reminder:** project 2 will not work unless project 1 is 100%. If you still need to fix up P1, come to office hours!

### Indexes vs. Filters

An <u>index</u> data structure of a subset of a table's attributes that are organized and/or sorted to the location of specific tuples using those attributes.

→ Example: B+Tree

A <u>filter</u> is a data structure that answers set membership queries; it tells you whether a key (likely) exists in a set but <u>not</u> where it is located.

→ Example: Bloom Filter

# **Today's Agenda**

**Bloom Filters** 

Skip Lists

Tries / Radix Trees

**Inverted Indexes** 

**Vector Indexes** 

## **Bloom Filters**

Probabilistic data structure (bitmap) that answers set membership queries.

- → False negatives will never occur.
- → False positives can sometimes occur.
- → See Bloom Filter Calculator.

#### Insert(x):

 $\rightarrow$  Use k hash functions to set bits in the filter to 1.

#### Lookup(x):

→ Check whether the bits are 1 for each hash function.

## **Bloom Filters**

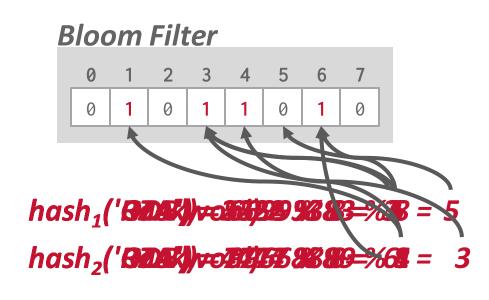

Insert 'RZA'

Insert 'GZA'

Lookup 'RZA' → TRUE

Lookup 'Raekwon' → FALSE

Lookup 'ODB' → TRUE

## **Bloom Filters**

#### False Negative Rate:

Probability that Insert(x) followed by Lookup(x) = False

After Insert(x), my bits are set forever

False Negative Rate = Zero (!)

#### False Positive Rate:

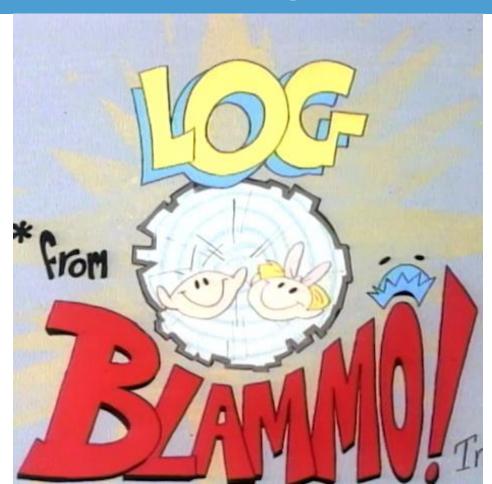

Probability Lookup(x) = True without Insert

Given m bits, storing n keys, with k probes per key:

What is Prob(n + 1st key gives false positive)? Not 0!

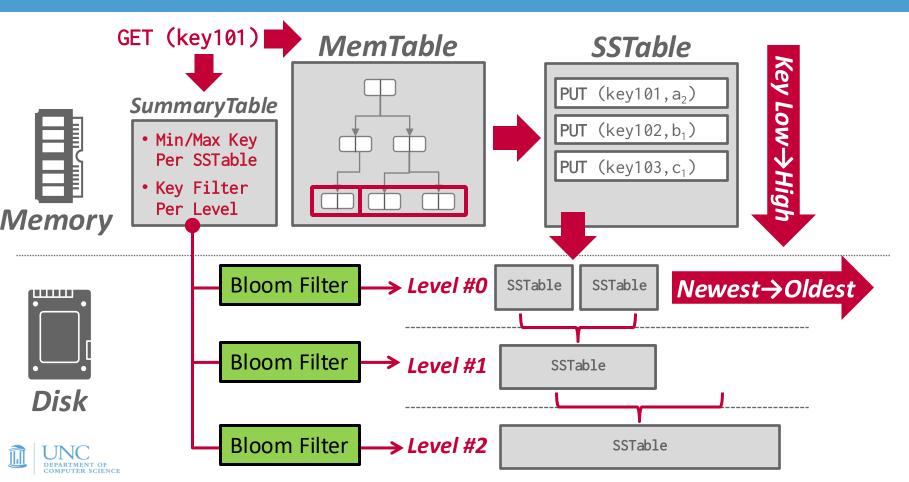

# It's Log!

## **Log-structured Storage**

## **Bloom Filter Math**

Prob(false positive) = Prob(pick k probes, all are 1)

Prob(false positive) = Prob(all k probes are 1 after n keys)

 $\approx$  Prob(one probe is 1 after n keys)<sup>k</sup>

Easier:

Prob(probe is 0 after 1 key) = 
$$\left(1 - \frac{1}{m}\right)^k$$

Prob(probe is 0 after n keys) = 
$$\left(\left(1 - \frac{1}{m}\right)^k\right)^n = \left(1 - \frac{1}{m}\right)^{kn}$$
  
=  $\left(\left(1 - \frac{1}{m}\right)^m\right)^{kn/m}$ 

## **Bloom Filter Math**

Prob(probe is 0 after n keys)= 
$$\left(\left(1 - \frac{1}{m}\right)^m\right)^{kn/m}$$
 (wat?)

$$\lim_{m\to\infty} \left(1 - \frac{1}{m}\right)^m = \frac{1}{e} \quad (!)$$

Prob(probe is 0 after n keys)  $\approx e^{-kn/m}$  for large m

Prob(Probe is 1 after n keys)  $\approx (1 - e^{-kn/m})$  for large m

Prob(All k probes are 1 after n keys)  $\approx \left(1 - e^{-\frac{kn}{m}}\right)^k$  for large m

- -Assumes some independence
- -Not needed to get a matching result with high probability using Hoeffding Bounds

-Interested? Take my grad class!

## **Bloom Filters IRL**

Given n, for any  $0 < \epsilon < 1$ , find smallest m such that:

$$\epsilon$$
 = Prob(All k probes are 1 after n keys)  $\approx (1 - e^{-kn/m})^k$ 

First, fix n, m and minimize w.r.t k,  $k^* = \frac{m}{n} \ln 2$ 

Next, for given n, using  $k^*$  probes, solve for  $m^*$ 

Optimal # bits per item to achive false positive rate  $\epsilon$ :

$$\frac{m^*}{n} \approx -2.08 \ln \epsilon$$

## **Bloom Filters IRL**

Optimal # bits per item to achive false positive rate  $\epsilon$ :

$$\frac{m^*}{n} = -\frac{\ln \epsilon}{(\ln 2)^2} \approx -2.08 \ln \epsilon$$

$$k^* = \frac{m}{n} \ln 2 = -\frac{\ln \epsilon}{\ln 2}$$

Why do this?

Time(insert) or Time(lookup) = 
$$O(k^*) = O\left(\log \frac{1}{\epsilon}\right)$$

Say I fix false positive rate of 1%:

$$\approx$$
 9.6 bits / item

$$\approx$$
 7 probes

For any number of keys!

sizeof(ptr)=32 bits

sizeof(char)=8 bits

## Other Fi

#### **Counting Bloom Filter**

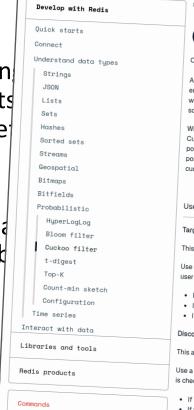

- → Supports dynamically addin
- → Uses integers instead of bits occurrences of a key in a set

#### **Cuckoo Filter**

- $\rightarrow$  Also supports dynamically  $\stackrel{\cdot}{\iota}$
- → Uses a Cuckoo Hash Table b of full keys.

## **Succinct Range Filter (Su**

→ Immutable compact trie th exact matches and range f

Docs → Develop with Redis → Understand Redis data types → Probabilistic → Cuckoo filter

#### Cuckoo filter

Cuckoo filters are a probabilistic data structure that checks for presence of an element in a set

A Cuckoo filter, just like a Bloom filter, is a probabilistic data structure in Redis Stack that enables you to check if an element is present in a set in a very fast and space efficient way, while also allowing for deletions and showing better performance than Bloom in some

While the Bloom filter is a bit array with flipped bits at positions decided by the hash function, a Cuckoo filter is an array of buckets, storing fingerprints of the values in one of the buckets at positions decided by the two hash functions. A membership query for item x searches the possible buckets for the fingerprint of x, and returns true if an identical fingerprint is found. A cuckoo filter's fingerprint size will directly determine the false positive rate.

Use cases

#### Targeted ad campaigns (advertising, retail)

This application answers this question: Has the user signed up for this campaign yet?

Use a Cuckoo filter for every campaign, populated with targeted users' ids. On every visit, the user id is checked against one of the Cuckoo filters,

- · If yes, the user has not signed up for campaign. Show the ad.
- If the user clicks ad and signs up, remove the user id from that Cuckoo filter.
- If no, the user has signed up for that campaign. Try the next ad/Cuckoo filter.

Discount code/coupon validation (retail, online shops)

This application answers this question: Has this discount code/coupon been used yet?

Use a Cuckoo filter populated with all discount codes/coupons. On every try, the entered code

- · If no, the coupon is not valid
- If yes, the coupon can be valid. Check the main database. If valid, remove from Cuckoo

## Indexes vs. Filters

An <u>index</u> data structure of a subset of a table's attributes that are organized and/or sorted to the location of specific tuples using those attributes.

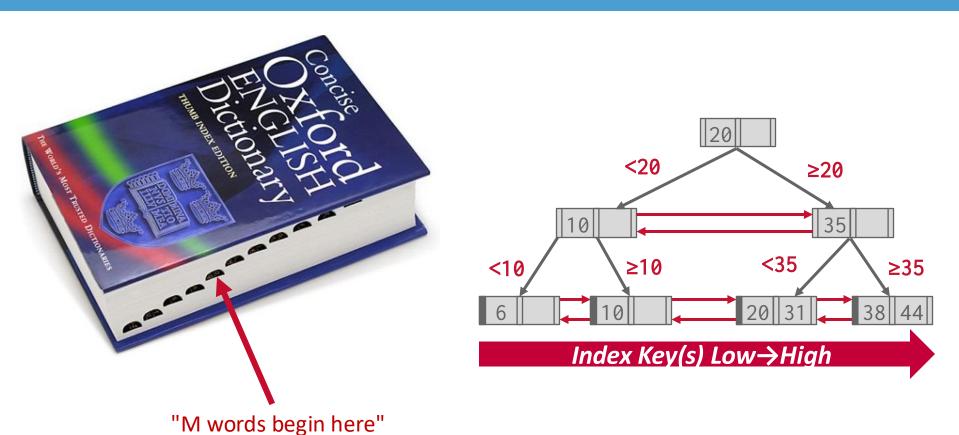

→ Example: B+Tree

A <u>filter</u> is a data structure that answers set membership queries; it tells you whether a key (likely) exists in a set but <u>not</u> where it is located.

→ Example: Bloom Filter

## **B+Trees as Fancy Linked Lists**

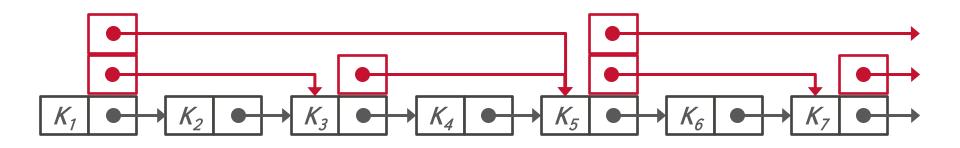

## **Observation**

Linked lists are "simplest" index, but...

All operations have to linear search.

- → Average Cost: O(n)
- → More than one way to index a linked list...

## **Skip Lists**

Multiple levels of linked lists with extra pointers to skip over entries.

- $\rightarrow$  1<sup>st</sup> level is a sorted list of all keys.
- $\rightarrow$  2<sup>nd</sup> level links every other key
- $\rightarrow$  3<sup>rd</sup> level links every fourth key
- $\rightarrow$  Each level has p fraction of the keys of one below it

Maintains keys in sorted order without requiring global rebalancing.

→ Want: O(log n) search times.

Mostly for in-memory data structures.

→ Example: LSM MemTable

Skip lists are a data structure that can be used in place of balanced trees. Skip lists use probabilistic balancing rather than strictly enforced balancing and as a result the algorithms for insertion and deletion in skip lists are much simpler and significantly faster than equivalent algorithms for balanced trees.

#### William Pugh

Binary trees can be used for representing abstract data types used as dictionates and ordered lines. They work well when the elements are inserted in a random coder. Some sequences of operations, used in secreting the elements in order, produce degenerate data structures that give very poor performance. If several content of the product of the produ

mucc. Sign fair are a probabilistic alternative to balanced trees. Sign fairs are a probabilistic alternative to balanced by committing a random number game to be a proper sign of the proper sign of the

Balancing a data structure probabilistically is easier than explicitly maintaining the balance. For many applications, skip lists are a more natural representation than trees, also leading to simple apportune. The subject of skip list algorithms makes them easier to implement and provides significant contant factor pool improvements over balanced tree and self-adjusting tree deportunes. Skip lists are also were an extension of the subject of the subjec

#### SKIP LISTS

We might need to examine every node of the list when search ing a linked list (Figure 1a). If the list is stored in sorted order and every other node of the list also has a pointer to the node two ahead it in the list (Figure 1b), we have to examine no more than | m2| + 1 nodes (where n is the length of the list). Also giving every fourth node a pointer four ahead (Figure 1e) requires that no more than  $Int^{14} + 2$  nodes be examined. If every ( $C_{\rm P}^{(3)}$  hoods has a pointer 2<sup>8</sup> nodes ahead (Figure 1d), the number of nodes that must be examined can be reduced to  $\log_2 n$  I while only doubling the number of pointers. This data structure could be used for fast searching, but insertion and deletion would be immerciate.

A mode that has forward pointers is called a level trook in Tevery (27%) onch has pointer? A mode about her levels of mode on deathward in a steeple pattern. 50% as level 1, and the pointer of mode on deathward in a steeple pattern. 50% as level 1, and the pointer of the control of the cont

#### SKIP LIST ALGORITHMS

SKIF LEVT ALGORITHMS.

The section give algorithm colls dath. Fine Score and deleter that the properties of the properties of the section of the properties of the properties

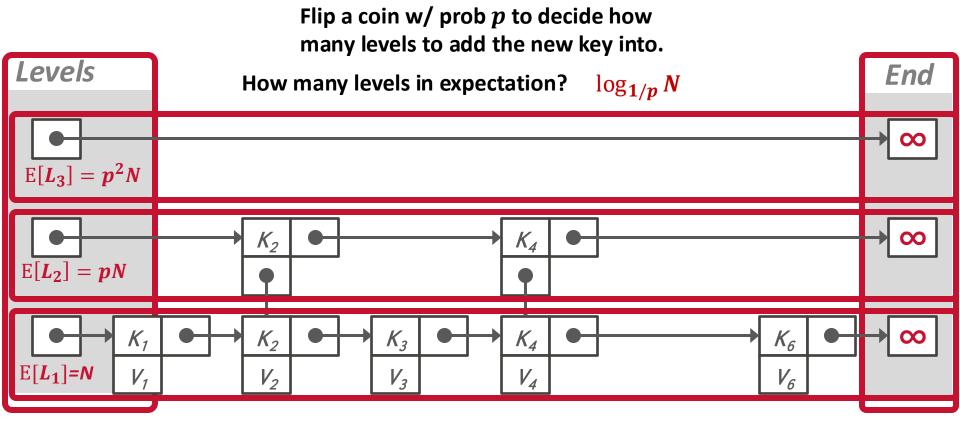

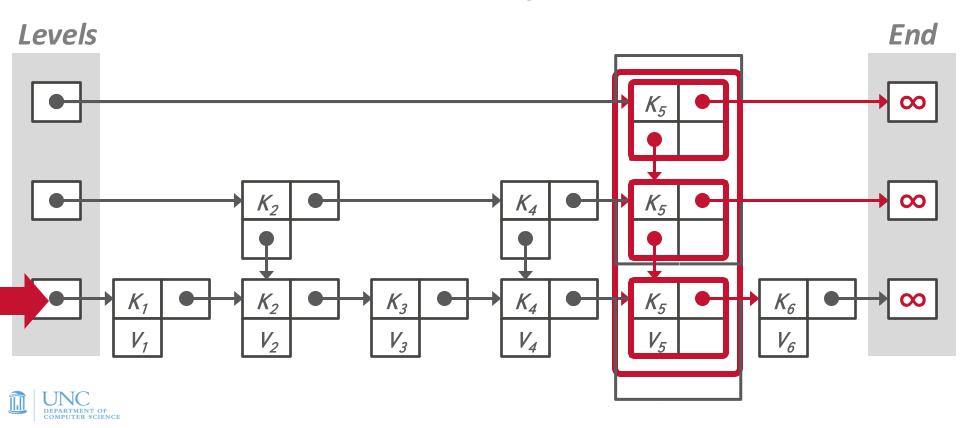

# **Skip Lists Basics**

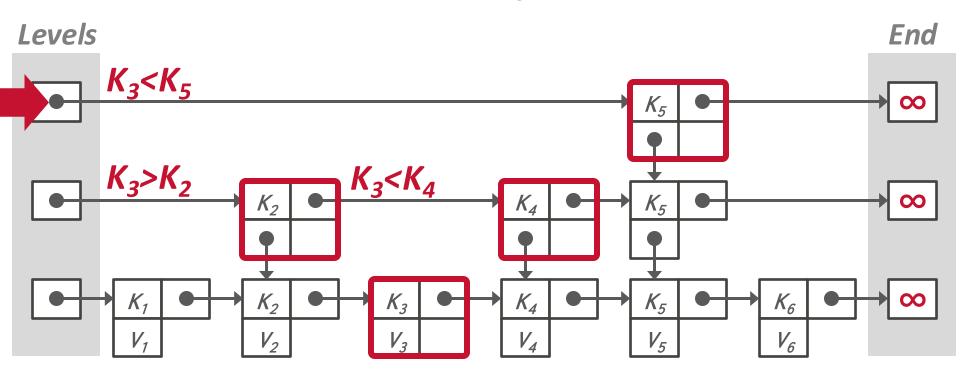

# **Skip Lists: INSERT**

Insert K<sub>5</sub>

## **Skip Lists: SEARCH**

Find K<sub>3</sub>

## **Skip Lists: DELETE**

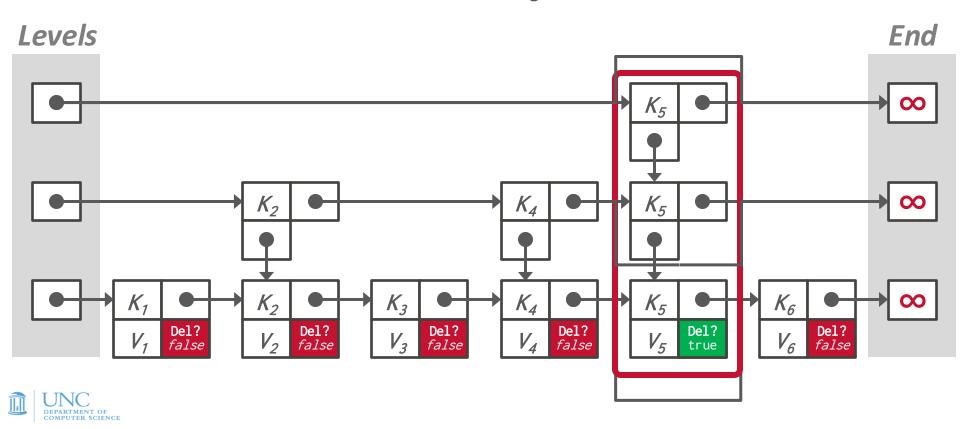

First <u>logically</u> remove a key from the index by setting a flag to tell threads to ignore.

Then **physically** remove the key once we know that no other thread is holding the reference.

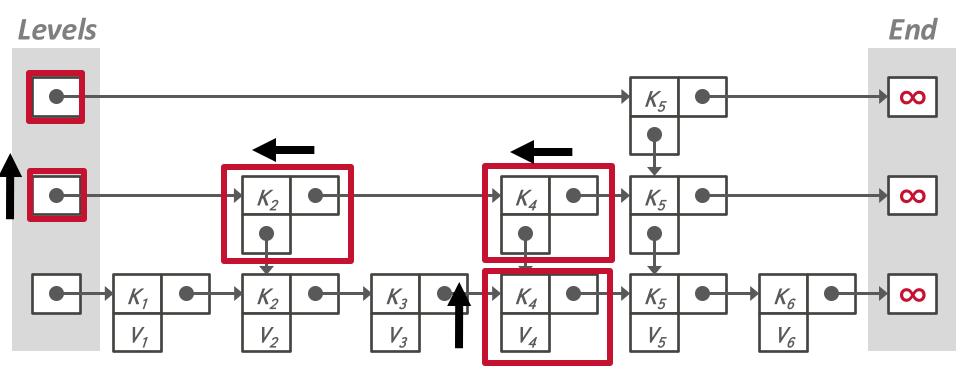

## **Skip Lists: DELETE**

## Delete K<sub>5</sub>

Find K<sub>4</sub>

**Question**: Expected length to traverse a skiplist with N keys and link probability p?

• Let *M* be random variable, path length

Break up the traversal path (moving backwards):

- Move left until up-link
- Move up one level, repeat
- Let  $M_i$  be # left steps before finding an up-link

Main idea: each link is independent, identically distributed w/ prob p

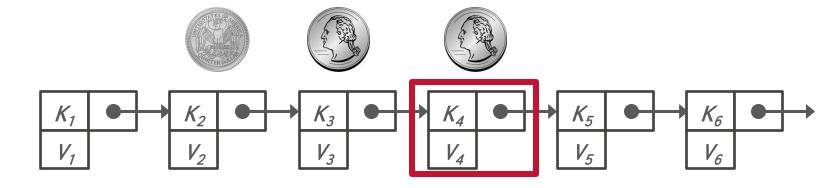

Question: Starting at any node, how many steps left until up-link?

**Question:** How many p-coin flips to get tails?

$$M_i \sim Geometric(p); Pr(M_i = x) = (1-p)^{x-1} p$$

$$E[M_i] = \sum_{x=1}^{\infty} x \cdot (1-p)^{x-1} p = \frac{1}{p} \text{ Left steps per up-link (expected)}$$

**Question**: Expected length to traverse a skiplist with N keys and link probability p?

$$E[M] = E[M_1 + M_2 + M_3 + \dots + M_{L-1}]$$

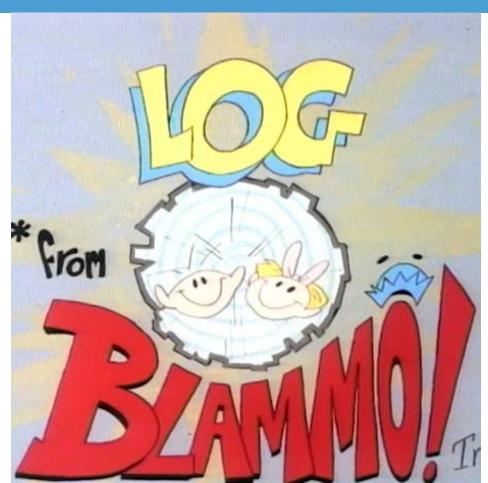

$$\approx E[M_i] \cdot E[\# Levels]$$

$$= \frac{1}{p} \cdot \log_{\frac{1}{p}} N = O(\log N)$$

In other words...

# It's Log!

# **Skip Lists**

#### **Advantages:**

- → Uses less memory than a typical B+Tree if you do <u>not</u> include reverse pointers.
- → Insertions and deletions do not require rebalancing.

#### **Disadvantages:**

- → Not disk/cache friendly because they do not optimize locality of references.
- → Reverse search is non-trivial.

We stopped here in class because I decided to focus more on the internals of Bloom filters and skip lists. The rest of these slides will not be covered, but cover some good-to-know data structures for indexing

## **Observation**

Both B+Trees and Skip Lists have the same weakness: Lookup(x) == full traversal

Lookup for keys that don't exist are slow

 "Negative caching", insert tombstone for objects that don't exist

**Want:** Best of both worlds. An index data structure with filter-like properties

## **Trie Index**

Use a digital representation of keys to examine prefixes one-by-one.

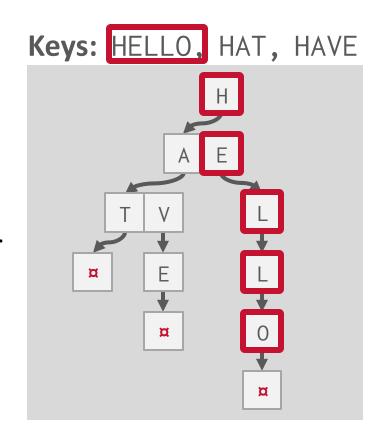

→ aka *Digital Search Tree, Prefix Tree*.

Shape depends on keys and lengths.

- → Does <u>not</u> depend on existing keys or insertion order.
- → Does <u>not</u> require rebalancing operations.

All operations have O(k) complexity where k is the length of the key.

- → Path to a leaf node represents a key.
- → Keys are stored implicitly and can be reconstructed from paths.

# **Trie Key Span**

The **span** of a trie level is the number of bits that each partial key / digit represents.

→ If the digit exists in the corpus, then store a pointer to the next level in the trie branch. Otherwise, store null.

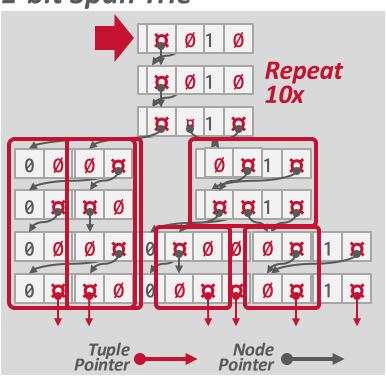

This determines the <u>fan-out</u> of each node and the physical <u>height</u> of the tree.

 $\rightarrow$  *n*-way Trie = Fan-Out of *n* 

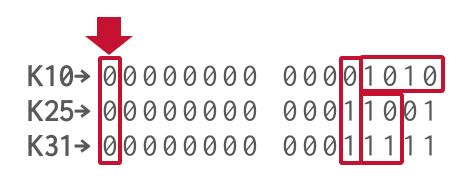

# **Trie Key Span**

#### 1-bit Span Trie

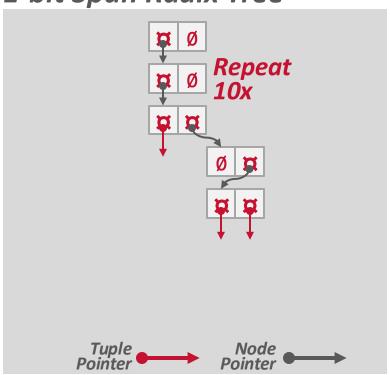

**Keys:** K10, K25, K31

## Radix Tree

1-bit Span Radix Tree

Vertically compressed trie that compacts nodes with a single child.

 $\rightarrow$  Also known as *Patricia Tree*.

Can produce false positives, so the DBMS always checks the original tuple to see whether a key matches.

HyPer () UMBRADuckDB () CedarDB

### **Observation**

The indexes that we've discussed are useful for "point" and "range" queries:

- $\rightarrow$  Find all customers in the 15217 zipcode.
- → Find all orders between June 2024 and September 2024.

They are **not** good at keyword searches:

→ Example: Find all Wikipedia articles that contain the word "Pavlo"

#### revisions(id,content,...)

CREATE INDEX idx\_rev\_cntnt
 ON revisions (content);

SELECT pageID FROM revisions
WHERE content LIKE '%Pavlo%';

#### **Inverted Index**

An **inverted index** stores a mapping of terms to records that contain those terms in the target attribute.

- → Sometimes called a *full-text search* index.
- → Originally called a *concordance* (1200s).

Many major DBMSs support these natively. But there are also specialized DBMSs and libraries. Term /

## **Inverted Index: Lucene**

Uses a Finite State Transducer for determining offset of terms in dictionary.

Incrementally create dictionary segments and then merge them in the background.

- → Uses compression methods we previously discussed (e.g., delta, bit packing).
- → Also supports precomputed aggregations for terms and occurrences.

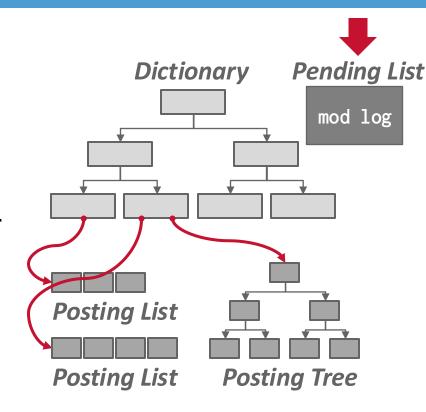

# Inverted Index: PostgreSQL

PostgreSQL's Generalized Inverted Index (GIN) uses a B+Tree for the term dictionary that map to a posting list data structure.

Posting list contents varies depending on number of records per term:

- → **Few**: Sorted list of record ids.
- → **Many**: Another B+Tree of record ids.

Uses a separate "pending list" log to avoid incremental updates.

#### **OBSERVATION**

Inverted indexes search data based on its contents.

- → There is a little magic to tweak terms based on linguistic models.
- → Example: Normalization ("Wu-Tang" matches "Wu Tang").

Instead of searching for records containing exact keywords (e.g., "Wu-Tang"), an application may want search for records that are related to topics (e.g., "hip-hop groups with songs about slinging").

### **Vector Indexes**

Specialized data structures to perform nearestneighbor searches on embeddings.

- → An embedding is an array of floating point numbers.
- → May also need to filter data before / after vector searches.

The correctness of a query depends on whether the result "feels right".

## **Vector Indexes: Inverted File**

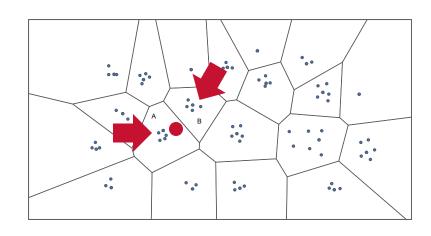

Partition vectors into smaller groups using a clustering algorithm.

To find a match, use same clustering algorithm to map into a group, then scan that group's vectors.

→ Also check nearby groups to improve accuracy.

Preprocess / quantize vectors to reduce dimensionality.

**Example: IVFFlat** 

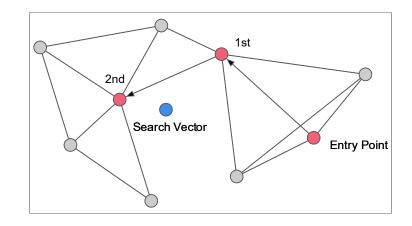

# **Vector Indexes: Navigable Small Worlds**

Build a graph where each node represents a vector and it has edges to its *n* nearest neighbors.

→ Can use multiple levels of graphs (<u>HNSW</u>)

To find a match for a given vector, enter the graph and then greedily choose the next edge that moves closer to that vector.

**Example:** Faiss, hnswlib

## Conclusion

We will see filters again this semester.

B+Trees are still the way to go for tree indexes.

We did not discuss geo-spatial tree indexes:

→ Examples: R-Tree, Quad-Tree, KD-Tree

## **Next Class**

How to make indexes thread-safe!

### **Leaderboard Results**

The top 20 fastest valid implementations in the class will receive extra credit for this assignment.

 $\rightarrow$  **#1:** 50% bonus points

→ **#2–10**: 25% bonus points

→ **#11–20**: 10% bonus points

Bonuses applied manually at the end. Best leaderboard performer gets swag/prize TBD
